## INTRODUCTION

This study is part of the **ANR ClostAbat project** titled "Characterization of the *Clostridium perfringens* and *Clostridioides difficile* hazards in the cattle, pig, and poultry sectors in slaughterhouses".

Clostridium perfringens is a spore forming anaerobic bacteria that is both an ubiquitous environmental bacteria and a foodborne pathogen. 74% of foodborne outbreaks caused by *C. perfringens* in France are associated with the use of contaminated raw materials to prepare mainly meat-based ready meals <sup>[1]</sup>. *C. perfringens* contamination in the food chain is suspected to occur during the evisceration step in slaughterhouses. However, very few studies have investigated the contamination origins for *C. perfringens*.

The objective of this study is to provide information on prevalence, diversity and pathogenic potential of the C. perfringens strains isolated from slaughterhouses.

## **METHODS**

#### Sampling

Strains will be isolated from 8 to 12 sampling campaigns in 3 sectors: pig, cattle, and poultry. Various types of samples: animal (feces, carcass, meat cuts), environment (work surfaces and operator tools) and air of slaughterhouses and cutting plants.

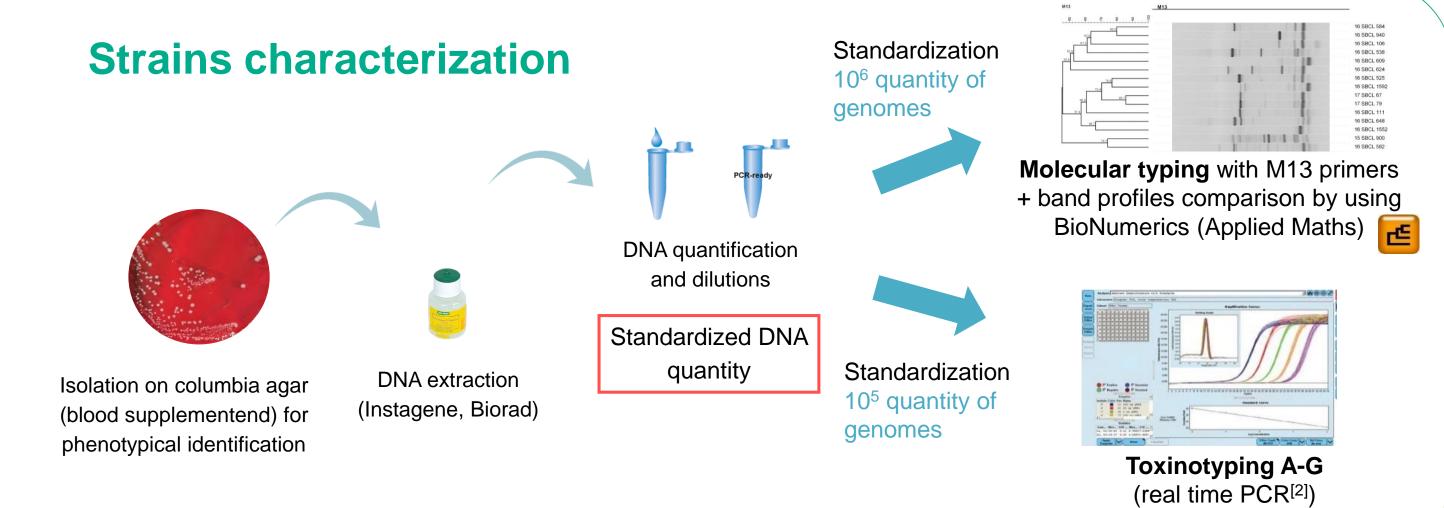

#### **Current sampling campaigns progress**

| Se of | 1 | 2 | 4 |   | 6 | 8  |    |
|-------|---|---|---|---|---|----|----|
|       | 1 | 2 | 4 |   | 6 | 8  |    |
| N.    | 1 | 2 | 4 | 6 | 8 | 10 | 12 |

Total isolated strains = 330

Total isolated strains = 42

Total isolated strains = 176

## RESULTS

| Н  | 2                    | Winter | 58               | 36               | 62                | 62                               | 46 ± 23                     |

*C. perfringens* prevalence varies by sector:

- The poultry sector has the highest prevalence of all sectors, with a mean prevalence of 46%.
- The mean prevalence for five sampling campaigns in the pig sector is 25%.

Diversity of *C. perfringens* strains is estimated by comparison of M13 band profiles.

In the pig sector, the diversity of isolates is high (> 40 M13 profiles). The number of distinct profiles increases further with the addition of new strains, suggesting that full diversity has not yet been achieved in this sector.

Conversely, in poultry sector, the diversity of isolates is low (15 M13 profiles). With 80 isolates from two sampling campaigns, the curve begins to flatten at the top, suggesting that full diversity has been achieved for this sector.

In cattle sector, the low number of isolates (25) from the three initial sampling campaigns does not allow to make any conclusion yet.

#### Toxinotype

Toxinotypes of strains confirmed to be different based on their typing profiles were determined. In pig and cattle sectors, strains are 100% type A. In poultry sector, strains are 76% type A and 24% type G.

Toxinotype of *C. perfringens* strains in pig (n = 125), cattle (n =29), and poultry (n = 63) sectors

|      | Sector | Toxinotype A<br>(%) | Toxinotype A <i>cpb2</i> +<br>(%) | Toxinotype G<br>(%) |
|------|--------|---------------------|-----------------------------------|---------------------|
| 70 2 |        |                     |                                   |                     |

 The cattle sector has the lowest prevalence, with a mean prevalence of 7% for three sampling campaigns.

# **DISCUSSION & CONCLUSION**

*C. perfringens* prevalence in slaughterhouses in pig, cattle, and poultry sectors are variable and ranges from 4% (cattle slaughterhouse) to 62% (poultry slaughterhouse). Strains diversity are estimated to be high for strains isolated from pig sector, and low for strains from poultry sector. As for toxinotype identification, *C. perfringens* strains are mainly type A. In poultry sector, there are also type G strains (24%). These results, combined with genome sequencing of selected *C. perfringens* isolates, will subsequently enable us to establish whether a relationship exists with strains involved in *C. perfringens*-related human infections.
